Subject: Cardel Creekside Ph 2 Subdivision – Water Balance Analysis

Introduction

JFSA Canada Inc. (JFSA) was retained by Robinson Consultants Inc. (RCI) to complete a water balance analysis for the Cardel Creekside Phase 2 Subdivision located at 2780 Eagleson Road in the City of Ottawa. This memo presents the water balance analysis under pre- and post-development conditions based on the latest proposed development plan and information provided by RCI.

The Creekside Phase 2 Subdivision is approximately **24.63 ha** and will be a mix of residential units and parklands. The subject site is bound by Eagleson Road to the east, existing properties fronting Perth Street to the south, Flowing Creek to the west and agricultural lands to the north. The subject land is predominantly agricultural and is located near the downstream end of Flowing Creek, close to its confluence with the Jock River. The following memo outlines the assumptions made and the results of this hydrologic water balance analysis.

Water Budget Modelling

To assess the water budget for the site under both pre- and post-development conditions, a continuous SWMHYMO model was developed. This model was run using 39 years of hourly rainfall data from the Ottawa International Airport from 1967 to 2007 (excluding missing 2001 rainfall data), the average annual evaporation, infiltration and runoff volumes from the subject site were computed and compared. Note that this rain gauge is generally only operational for the months of April-November. Outside of this window precipitation is more likely to be in the form of snowfall and the soils are also more likely to be frozen, making it difficult to simulate such conditions with a hydrologic model using conventional City parameters, as such, this period has not been considered in the analysis. Note that the same simulation window has been applied for both pre- and post-development conditions, so although this is not a complete annual analysis of the site's water budget, it is a reasonable quantification of the development impacts during a period when the hydrologic operations of the site are well understood.

Continuous hydrologic simulations were also performed with a CN of 99.99, to simulate the runoff from the subject site if no infiltration occurs. The difference between the runoff simulated with the actual CN and the runoff simulated with the CN of 99.99, is equal to the infiltrated volume over the subject site. The remaining volume (total rainfall – infiltration & runoff) was then calculated to determine the evaporation that occurs annually within the site. Note that “evaporation” in this memo refers to all losses that return to the atmosphere and includes both evapotranspiration and wetting losses (e.g. initial abstraction).

Model Parameters

Typical model parameters have been applied to the model as per the City of Ottawa Guidelines, for example, Initial Abstraction (IA) values for pervious and impervious surfaces have been considered **4.67mm** and **1.57 mm** respectively under post-development conditions. Although, there are additional simulation parameters required to complete continuous simulations using SWMMHYO that are not specified in the City of Ottawa Storm Sewer Guidelines. The following tables outline these parameters and the justification for the values selected.

Table 1: Continuous Simulation Parameters

Parameter(s) & Value(s)	Description
APII=[50], APIK=[0.90]/day	Used to compute the Antecedent Precipitation Index during the continuous simulation. Without model calibration, these are the default values.
SMIN=[-1], SMAX=[-1](mm)	The negative values indicate that the storage volume in the SCS procedure will vary between the "S" determined for AMC I and AMC III conditions of the entered CN value in undeveloped and urban areas.
SK=[0.3]/(mm);	A calibration coefficient that can typically vary from 0.01 to 0.3 for undeveloped and urban areas. The higher the value, the more runoff is generated.
IaRECper=[6](hrs);	The time that it takes for the Initial Abstraction over pervious areas to recover during a dry period in urban areas.
IaRECimp=[3](hrs);	The time that it takes for the Initial Abstraction over impervious areas to recover during a dry period in urban areas.
InterEventTime=[12](hrs)	The continuous dry time is required to reset the parameters in the SCS procedure to their initial values.

Soil Infiltration Rate

Based on the Soil Survey Complex Data produced by OMAFRA and publicly available on Land Information Ontario (LIO), the soil within the site is considered to be a **Type D** SCS hydrologic soil group, which is characterized by soils that have a very slow infiltration rate when thoroughly wet. These soils have a high runoff potential and are typically composed of clay soils. A soil infiltration rate of **15 mm/hr** with a reduction factor of **2.5**, which results in an adjusted infiltration rate of **6 mm/hr** has been assumed in this study and applied to the rear yard infiltration trenches/LIDs under post-development conditions.

Pre-Development Conditions

Soil data within the study area has been taken from Soil Survey Complex Data produced by OMAFRA. **Figures A1** and **A2** in **Attachment A** provides a visual overview of the various drainage areas within the site under existing conditions. **Figure A3** in **Attachment A** outlines soil type data for the study area. The underlying Land Use for the respective areas was extracted from the Southern Ontario Land Resource Information System (SOLRIS) GIS layer, also publicly available on Land Information Ontario (LIO). **Figure A4** in **Attachment A** was merged with the underlying soil types to derive a Curve Number (CN), based on applicable values outlined in **Tables A2** and **A3** of the SWMHYMO Manual. Each Curve Number was then weighted based on the total area within a given subcatchment to determine the weighted CN for that subcatchment, see **Table A1** in **Attachment A**.

The time-to-peak values have been calculated based on existing topography using the City of Ottawa LiDAR publicly available on Land Information Ontario (LIO). Flow paths have been discretized based on the topographic data using GIS tools and the longest major flow path was identified; **Figure A5** in **Attachment A** outlines the flow path discretization. The upstream and downstream topographic elevations and flow lengths were identified and used in the calculations. For these natural subcatchments, the Federal Aviation Administration (FAA) Method was used to calculate the Time to Peak (t_p). **Table A2** in **Attachment A** provides full details of these calculations, along with other time-to-peak values using alternative t_p calculation methods.

An initial abstraction (IA) value of **7mm** (IA ~ 0.10 S) and typical continuous simulation parameters were applied to the pre-development conditions model. The model was run using 39 years of continuous rainfall data and the average annual evaporation infiltration and runoff volumes were calculated. Based on the pre-development simulation results shown in **Table 2** below, it was found that under pre-development conditions this site will evaporate/evapotranspire **58% (297 mm/year)** of the annual precipitation, infiltrate **25% (125 mm/year)** of the annual precipitation, with the remaining **17% (89 mm/year)** of the precipitation running off the site. The full SWMHYMO input and summary modelling files, as well as annual water budget breakdowns have also been provided in **Attachment A**.

Post-Development Conditions - With Rear Yard Swales/Infiltration Trenches

The increase in the impervious area due to the proposed development will decrease annual infiltration volume. To help offset this deficit, several of the residential lots will have rear yard swales/infiltration trenches, which will return clean runoff into the soils.

City of Ottawa default initial abstraction values and typical continuous simulation parameters were applied to the post-development conditions model. As the rear yard swales operate with a free outlet, the percentage of runoff volume that is captured by these trenches and that can pass through the perforations within the subdrain has been calculated per **Equation 4.18** of the MECP March 2003 Stormwater Management Planning and Design Manual. Based on this analysis, **37%** of the total flow captured by these rear yard ditches will be conveyed to the trench, with the rest free passing to the outlet of the pipe. A **DIVERT HYD** command has been implemented in the post-development conditions model to simulate this flow split. The proposed rear yard trenches have been represented in the SWMHYMO model using a **ROUTE RESERVOIR** command. These commands represent the total storage volume within the proposed trenches and the exfiltration through the trenches. See **Table B1** in **Attachment B** for full details of the trench representation in the model. The full SWMHYMO input and summary modelling files, as well as annual water budget breakdowns have also been provided in **Attachment B**.

Based on the post-development simulation results shown in **Table 4** below, it was found that under post-development conditions with consideration for the infiltration trenches, the site will evaporate/evapotranspire **31% (158 mm/year)** of the annual precipitation, infiltrate **22% (112 mm/year)** of the annual precipitation, with the remaining **47% (241 mm/year)** of the precipitation running off the site. As can be seen, evaporation reduces under post-development conditions when compared to pre-development conditions, which is expected due to the increase in impervious surfaces, reduction in vegetation, etc. that occurs under post-development conditions. This is in line with the information shown in Table 1.1 of the March 2003 **Ontario Ministry of the Environment (MOE) Stormwater Management Planning and Design Manual**. By comparing the post-development conditions with and without the infiltration trenches, it is seen that they increase the annual infiltration volume for the site by **31 mm/year**, which equates to an additional **7,635m³** of runoff volume per year infiltrated.

Development Water Balance Scenario Summary

Tables 2, 3 & 4 summarize the annual average water balance under pre-development/existing conditions and post-development conditions for the proposed development lands without and with rear yards swales in place, as m³/year, mm/year and % of total annual rainfall.

Table 2: Pre-Development Water Balance

Annual Average Volume	Precipitation	Evapotranspiration	Infiltration	Runoff
mm	511	297	125	89
m ³	125,766	73,064	30,790	21,913
%	100%	58%	25%	17%

Table 3: Post-Development Water Balance – Without Rear Yard Swales

Annual Average Volume	Precipitation	Evapotranspiration	Infiltration	Runoff
mm	511	158	81	272
m ³	125,766	38,834	19,973	66,959
%	100%	31%	16%	53%

Table 4: Post-Development Water Balance – With Rear Yard Swales

Annual Average Volume	Precipitation	Evapotranspiration	Infiltration	Runoff
mm	511	158	112	241
m ³	125,766	38,834	27,563	59,369
%	100%	31%	22%	47%

Based on this analysis, under pre-development conditions this site will evaporate **58%**, infiltrate **25%** and runoff **17%** of all annual rainfall. Under post-development conditions with consideration of rear yard swales, this site will evaporate **31%**, infiltrate **22%** and runoff **47%** of all annual rainfall. Under post-development conditions with consideration for the rear yard swales, the annual infiltration volume will on average be **112 mm/year**, representing a reduction of approximately **10%** when compared to the pre-development conditions.

Conclusion

A detailed water balance analysis of the existing site was completed to determine pre-development infiltration rates. A post-development analysis for the site showed that the percentage of annual rainfall infiltrated would decrease by **10%** compared to the volume infiltrated under pre-development conditions. Based on this analysis, the impact of the proposed development on groundwater recharge has been quantified.

Yours truly,

```

Table with columns for file names, sizes, dates, and various metadata fields. The table is organized into four columns. The first column contains file names and sizes, the second column contains dates and times, and the subsequent columns contain various metadata fields such as permissions, owner, and group.

Table with columns: ID, Description, Value, and Unit. The table contains multiple rows of data, including calculations for areas, perimeters, and various flow rates. It includes section headers such as 'CONTINUOUS STANDYD' and 'CONTINUOUS STANDBYD'.

Table with columns for station ID, component name (e.g., CONTINUOUS STANDBYD, DIVERST HYD, ROUTE RESERVOIR), flow direction (e.g., to, from, out, in), and numerical values. The table contains multiple sections for different components and flow directions, with some rows marked as '*****'. It lists various flow paths and their associated values, such as 17, 0.04, 1978.0618, 1700, 229.70, 449, .000.
