1.0 INTRODUCTION

WalterFedy has been retained by Enbridge Gas Inc. to provide consulting engineering services in support of the proposed construction of a replacement Operations Centre located at 2571 Lancaster Road in Ottawa. The proposed development site will amalgamate with the 2595 Lancaster Road property, which is located behind the existing building to the north and is an abandoned Canadian National Railway corridor. The amalgamated property will be known municipally as 2571 Lancaster Road.

The purpose of this Functional Servicing and Stormwater Management Report is to identify how the development will be serviced, including water, sanitary, and storm connections to the existing municipal infrastructure. The report will discuss existing servicing conditions surrounding the site and the available capacity in the municipal system to determine how it will accommodate the development. Preliminary stormwater management design has been presented, demonstrating consistency with the City of Ottawa's design criteria.

1.1 Background

The property located at 2571 Lancaster Road has a site area of approximately 1.67 hectares and is zoned Light Industrial (IL). The other property at 2595 Lancaster Road has a site area of 1.63 hectares, for a combined project site area of 3.3 hectares. The overall project site is zoned both IL and IH (Heavy Industrial). Upon completion of the amalgamation process the site is accessed from Lancaster Road to the south, and is bound by tennis courts to the west, a commercial plaza to the east, and industrial buildings to the north.

The southern parcel is currently occupied by The Minto Skating Centre, which is an ice hockey rink, and associated surface parking. The northern parcel exists as an abandoned Canadian National Railway line that appears to have transformed into an overgrown grassy and bush area.

The proposed development is expected to consist of a building that will include office space, a warehouse, and a workshop. The development will also include associated surface parking and outdoor storage space. The outdoor storage space is not permitted within IL zoning, so it is proposed to be constructed within the IH area. The proposed building is expected to have a total floor area of approximately 4815 m^2.

2.0 EXISTING INFORMATION

2.1 Existing Topography

The site is currently occupied by The Minto Skating Centre in the southern parcel, and overgrown grass and bush in the northern parcel. A topographic and legal survey was completed by J.D. Barnes Limited in May 2021.

The elevation of the site ranges from approximately 68.0 m at the southwestern corner of the site to approximately 68.3 m at the southeastern corner. The western, eastern, and northern property lines for the 2571 Lancaster Road property stay relatively consistent at an elevation of 68.0 m. The existing building sits in the middle of the site, and the finished floor elevation at the front of the building is approximately 71.0 m. The elevations at the rear of the building are approximately 68.0 m. The site currently drains to multiple catch basins sitting at low points within the asphalt areas surrounding the building.

2.2 Geotechnical Report

A geotechnical investigation was completed by Malroz Engineering Inc. to determine subsurface information for the site, including soil and groundwater depths and condition. A total of 13 boreholes were advanced (BH1-BH11 and MW5-21 and MW6-21), with seven of them within the abandoned railway corridor, and the two monitoring wells and the other four boreholes within the pavement area surrounding the building.

The boreholes advanced within the former railway corridor generally found a surficial topsoil layer of up to 0.5 m, underlain by sand and gravel fill, and then native clay extending to termination depth. The fill material depth ranges between 0.6 m and 1.4 m below grade. The boreholes were terminated 2.9 m below grade.

The other six boreholes advanced within the existing asphalt area encountered approximately 50 mm of asphalt, underlain with approximately 0.8 m of granular base materials. Beneath the pavement structure is a layer of silty clay and then a layer of sandy silty clay / silt gravelly sand. Limestone bedrock was encountered in boreholes BH09 and BH11 at depths of 2.9 m and 6.1 m, respectively. Boreholes BH08 and BH10 were terminated 4.2 m below grade in sandy silty clay due to auger refusal. The boreholes associated with MW5-21 and MW6-21 were terminated 4.9 m and 3.8 m below grade, respectively.

Groundwater was observed through the two monitoring wells on two separate dates in April 2021, approximately a week apart. On the first observation day, groundwater was at an elevation of approximately 66.7 m at MW5-21, which is located near the northwestern corner of the existing building. At MW6-21, the groundwater was at an elevation of approximately 65.9 m, which is near the southeastern corner of the site. On the second observation day, the groundwater at MW5-21 was at an elevation of approximately 66.2 m, and 66.4 m at MW6-21. It should be noted that groundwater levels can vary seasonally and in response to major weather events.

2.3 Existing Servicing and Utilities

Existing services on and around the site were document by J.D. Barnes Limited during their topographic survey, and supplemental information was obtained from City of Ottawa GIS information available online.

Surrounding the existing building, there are multiple catchbasins located in low spots to collect runoff from the asphalt and landscaped areas within the 2571 Lancaster Road parcel. There are two separate storm outlets, one at either side of the building. Both of these outlets are a 375-mm-diameter pipe that appears to blind connect to the municipal infrastructure. The municipal storm sewer is a 675-mm-diameter concrete sewer sloped at 0.3%.

An existing water service exists within the western driveway and conveys water to a hydrant at the rear of the building. A domestic service branches off this watermain near the front of the building. The existing municipal watermain on Lancaster Road is a 305-mm-diameter ductile iron pipe. There is also a municipal hydrant on Lancaster Road fronting the site.

A 375-mm-diameter municipal sanitary sewer exists within Lancaster Road. It is presumed that the sanitary outlet from the site blind connects into this municipal sewer.

The site also has hydro, telecommunication, and gas services from Lancaster Road.

Services for the 2595 Lancaster Road parcel include a bell telecommunications line running east-west, and a 600-mm-diameter storm culvert. Existing drainage paths and flow regimes within this portion of the property are undefined with no readily-apparent, positive outlet. It is likely that neighbouring properties are draining onto the 2595 lands illegally as a result of previous unregulated development works. The Owner and their legal counsel have had conversations with the neighbours to notify them of these conditions and advised them to address their drainage accordingly. Appropriate documentation in the form of notice letters or communication records can be provided if required.

3.0 SANITARY SERVICING

The *City of Ottawa Sewer Design Guidelines* (October 2015) stipulate that the average daily sanitary demand for light industrial developments is 35,000 L/gross ha/day. Although the site is zoned for both Heavy Industrial and Light Industrial uses, the areas of the site producing the sanitary flows are located within the Light Industrial parcel only for both existing and proposed conditions. Sanitary demand calculations for the site have been developed based on this condition, with the IH portion of the parcel excluded. The average daily sanitary flows from industrial developments are to be peaked with a factor of 6.0 according to Appendix 4-B.1 of the Guidelines. An extraneous flow allowance of 0.33 L/s/effective gross area is to be included in the peak flow rate calculation. Refer to Table I below for a summary of the peak sanitary flow rate from the site.

Table I: Sanitary Demand

Site Area	1.67 ha
Light Industrial Average Daily Flow	35,000 L/ha/day
Peaking Factor	6.0
Peak Design Flow	**4.06 L/s**
Extraneous Flow Allowance	0.33 L/s/ha
Total Extraneous Flow	**0.55 L/s**
Total Sanitary Flow from Site	**4.61 L/s**

The design peak flow rate for proposed conditions is the same as the design peak flow rate for existing conditions, which is approximately 4.61 L/s. The 1.63 hectares of land from 2595 Lancaster Road IH zoned parcel were omitted as there is no sanitary sewer or development within its property limit in existing or proposed conditions. As no sanitary pipework is proposed on the IH portion of the parcel it is assumed that wet weather flows from this area will not be collected by the sanitary service for the site, and they will continue to drain naturally as they do in the existing condition. Refer to Appendix A for the sanitary design calculations.

The existing sanitary outlet from the site to the municipal sewer was not picked up as part of the topographical survey. However, it will be removed and replaced with a new connection to service the proposed building. The proposed service will be a 150-mm-diameter PVC sewer at 2.0%, and an inspection manhole will be installed inside the property line. The proposed service will also be equipped with a backwater valve.

4.0 WATER SERVICING

4.1 Design Criteria

The *Ottawa Design Guidelines – Water Distribution* (July 2010) references the MECP guidelines for watermain pressure requirements for proposed developments. It is recommended that, under normal operating conditions, pressure within water distribution systems ranges between 350 kPa (50 psi) and 550 kPa (80 psi).

The guidelines also state that, under the maximum hourly demand condition (non-fire scenario), the resultant pressure within the water distribution system shall not be less than 275 kPa (40 psi). With the inclusion of fire flows, the minimum residual pressure in the distribution system shall not be less than 140 kPa (20 psi). The maximum pressure in the distribution system shall never exceed 700 kPa (100 psi) under any scenario within the right-of-way. Within the site boundaries, the Ontario Building Code states that the maximum pressure in the distribution system shall not exceed 550 kPa (80 psi).

4.2 Domestic Water Demand

Calculations of the water demand for the site have been determined using the guidelines outlined within the *Ottawa Design Guidelines – Water Distribution* (July 2010). In accordance with these guidelines, the average day demand for light industrial sites is 35,000 L/gross ha/day. Domestic water servicing has been accounted for in the same manner as the sanitary generation for the site. The IH portion of the parcel has been omitted as there is no demand generated in that area. The guidelines also state that a peaking factor of 1.5 is to be used to determine the maximum day demand, and a peaking factor of 1.8 is to be applied to determine the maximum hour demand. Table II summarizes the water demand for the site.

Table II: Domestic Water Demand

Site Area	1.67 ha
Light Industrial Average Day Demand	35,000 L/ha/day
Site Average Day Demand	58,450 L/day
Average Day Demand (based on 16hr operating day)	1.0 L/s
Maximum Day Peaking Factor	1.5
Maximum Hour Peaking Factor	1.8
Maximum Day Demand	**1.01 L/s**
Maximum Hour Demand	**1.22 L/s**

The maximum day domestic demand for the site is approximately 1.01 L/s, and the maximum hour demand is approximately 1.22 L/s. Refer to Appendix B for the domestic water demand calculations. It should be noted that the 2595 Lancaster Road parcel of land was not included, as it will not house any buildings or consume any water.

4.3 Fire Flow Demand

In addition to the daily demand from the proposed development, fire flow demands are required to assess the adequacy of any proposed watermain system. The City of Ottawa specifies that all fire flow requirements shall be determined in accordance with the current issue of *Water Supply for Public Fire Protection* published by the Fire Underwriters Survey, and the Ontario Building Code. Because of this stipulation, it is necessary to determine if buildings are to be protected by sprinkler systems, as the resulting requirement for fire flow is calculated differently for buildings with or without sprinkler systems. Based on the Building Code Analysis, it is noted that the proposed building will be fitted with sprinkler systems. As such, the fire flow will need to be designed per NFPA 13 *Standard for Installation of Sprinkler Systems* (2013), which stipulates the criteria used for determining fire flow for buildings with sprinklers.

The fire flow demands for the proposed building is presented in Appendix B and summarized below.

Table III: Fire Flow Demand

Type of Construction	Non-Combustible Construction (C=0.8)
Occupancy Charge	Limited-Combustible Construction (-15%)
Automated Sprinkler Protection	Yes
Designed to NFPA 13 Standard	Yes (-30%)
Standard Water Supply to Sprinklers and Standpipes	Yes (-10%)
Fully Supervised System	Yes (-10%)
Exposure Charge (South – 2540 Lancaster Road)	35m (+5%)
Fire Demand	**100 L/s (1585 usgpm)**

The expected fire demand for the proposed building is expected to be 100 L/s. The existing building on the site has a greater floor space (6600 m^2) than the proposed building, and would have additional exposure charges due to proximity to the building to the east. Therefore, the fire demand for the proposed development is calculated to be less than the existing fire demand. A preliminary fire hydrant flow test completed by Troy Life & Fire Safety noted an available flow of 573 USGPM at 61PSI.

4.4 Service Design

As per the City of Ottawa design guidelines, the water service shall be able to convey the combination of the Basic (Maximum) Day Demand and the Fire Demand, within the pressure and velocity ranges as specified. For the proposed developed, this combined flow rate is approximately 101.01 L/s. To accommodate this flow, a minimum 200-mm-diameter water service is required. Since this demand is less than the demand for the existing building, there will be adequate availability within the municipal watermain to service the proposed development.

5.0 STORM SERVICING AND STORMWATER MANAGEMENT

5.1 Stormwater Management Objectives and Design Criteria

As per City of Ottawa regulations, the following stormwater management (SWM) criteria are applicable:

- Flows to the storm sewer in excess of the 2-year storm release rate, up to and including the 100-year storm event, must be detained on-site; and
- The allowable runoff coefficient (C) utilized to determine the pre-development release rate shall be the lesser of the existing calculated C for the site, or a maximum of 0.5.
- City of Ottawa Requirements dictate Level 1 “Enhanced” water quality.

Rideau Valley Conservation Authority (RVCA) did not provide a water quality criterion for the site.

5.2 Storm Sewers

The preliminary storm sewer layout and drainage areas for the proposed development are illustrated on Drawing C3-1. The storm drainage design will utilize the minor/major storm design principles. Runoff up to and including the 2-year return period peak flow, as calculated using the Rational Method, and using an inlet time of concentration of 10 minutes, will be conveyed through the underground storm sewer system to the proposed

SWM underground detention facility. Storm sewer capacity calculations will be provided at the detailed design stage. A minimum slope for the storm sewers of 0.15% was used for design purposes and a maximum flow rate-to-full flow capacity ratio of 1.00 was used. Storms exceeding the capacity of the storm sewer system will flow overland via the parking lot to the proposed underground storage tanks or to the former rail corridor.

5.3 Stormwater Management

5.3.1 Hydrologic Analysis

A hydrologic model was developed using PCSWMM and was used to calculate the runoff volumes and peak flows in pre- and post-development conditions for the various design storms as defined by the City of Ottawa. Appended Table C-1 presents a summary of the design storms simulated in PCSWMM including storm duration, maximum rainfall intensity, and total rainfall depth. Figure 1 presents the pre-development drainage areas and Figure 2 presents the post-development drainage areas used in the hydrologic modelling. Table C-2 presents the sub-catchment parameters used in the hydrologic modelling. Tables C-3 and C-4 present the summary of the runoff volumes and peak flows, respectively, as calculated using the hydrologic model. Table C-5 presents the pond stage-area-storage relationship developed to represent the proposed Cultec underground storage chamber in the model. Table 6 presents a summary of the hydrologic routing performance of the proposed SWM pond for each of the simulated design storms.

5.3.2 Water Quality Control

The City of Ottawa requires a Level 1 "Enhanced" water quality control protection, specifying a long-term annual average total suspended solids (TSS) removal rate of at least 80%. The proposed oil/grit separator will be sized at the detailed design stage to provide this TSS removal rate in accordance with the recommendations in the *Stormwater Management Planning and Design Manual* (MECP, 2003).

5.4 Storm Servicing and Stormwater Management Strategy

To meet the 2-year pre-development peak flow rates, on site stormwater storage is proposed. A combination of underground storage chambers and surface ponding in the proposed parking lot will provide the required detention volume. A 200-mm-diameter orifice plate will be utilized to control the peak outflow from the site. Additional details of the underground storage chamber system will be provided at the detailed engineering design phase.

The existing storm sewer service connections are proposed to remain. The new on-site storm sewer drainage and storage system will connect to the existing service stubs at the property line. An oil-grit separator will be sized during the detailed design to provide TSS removal from the parking lot, although not explicitly required by the RVCA.

A summary of the modeling results is provided below. Additional details can be found in Tables C1-C6 located in Appendix C.

Table IV: Stormwater Management Summary

Surface Storage Volume	1140 m^3
Underground Storage Volume	**712** m^3
Total Storage Volume Provided	**1852** m^3
Maximum Storage Volume Used	**1314** m^3
Control Orifice Diameter	**200 mm**
Allowable Site Release Rate (2-year pre-development event)	**347 L/s**
Maximum Actual Site Release Rate (100-year post-development event)	**329 L/s**

6.0 SITE GRADING

The grading of the site will respect the existing grades along all property lines, with driveways matching into existing edge-of-asphalt elevations on Lancaster Road. The site will also be graded to comply with City of Ottawa and the Accessibility for Ontarians with Disabilities Act (AODA) requirements.

Grading of the site will also allow for a major overland flow path from within the site to Lancaster Road, while ensuring maximum ponding depth is limited to 30 cm or less.

6.1 Compliance with On-Site and Excess Soil Management Provincial Regulations

The MECP regulation O.Reg. 406/19 "On-Site and Excess Soil Management" under the Environmental Protection Act states that the excavation of excess material, and subsequent off-site disposal of excess soils from this site, will require testing and reporting in the MECP's Environmental Activity and Sector Registry (EASR). While soil removal for the site is not currently anticipated as a requirement, the contractor and geotechnical engineer will be responsible to meet the above noted requirements in the event material requires removal from site.

7.0 EROSION AND SEDIMENT CONTROL

Any sediment tracked onto the roadway during the course of construction will be cleaned by the Contractor. To help minimize the amount of mud being tracked onto the roadway, a mud mat will be installed at the primary construction exit. Additionally, silt fence will be installed around the entire site to eliminate any sediment from leaving the site and will remain in place and be maintained until landscaping has been completed and soil has been vegetated. Silt fence will also be installed around any stockpiles on site, with the stockpiles kept a minimum 2.5 m from the property boundary.

Silt sacs in catchbasins will be installed to prevent silt- or sediment-laden water from entering inlets. These will be inspected to ensure that they have been properly installed and function as designed throughout construction.

The controls will be maintained, and accumulated sediments removed once their capture capacity has been decreased by one third. It is proposed that, during construction activities, visual monitoring will be conducted bi-weekly and within 24 hours of any rainfall event of 25 mm or greater. During the construction period, monitoring will consist of visual observation for the effectiveness of the sediment and erosion controls and sediment migration off site. Construction inspections will be conducted until such time as the construction activities are complete and vegetation has established itself.

8.0 CONCLUSIONS

Based on the analysis presented in this report, it is concluded that:

- The sanitary sewer on Lancaster Road has sufficient capacity to accommodate sanitary drainage from the proposed development as the design flow remains unchanged from existing conditions. A 200-mm-service at 2.0% can service the proposed development.
- The domestic and fire demand for the proposed development can be accommodated by a 200-mm-diameter service connected to Lancaster Road.
- A 200-mm-diameter flow control orifice in addition to the underground storage system controls the maximum peak flow rate from the site to 329 L/s to meet the required allowable release rate of 347 L/s.
- Surface ponding and underground storage chambers provide a total detention volume of 1852 m^3 on-site.

- Water quality control is not required by RVCA. Water quality measures to meet City of Ottawa requirements will be incorporated during detailed design.
- Site grading will allow for a major overland flow path to the former rail corridor to match existing drainage patterns and directions, and ensure surface ponding does not exceed 30 cm.
- Perimeter silt fence, silt fence at the base of all stockpiles, silt sacs in catchbasins, and construction entrance mud mats can provide erosion and sediment control. These will be included in detailed design in coordination with the proposed construction staging plan.
